Abstract: If a nearly natural population system is deviated from its equilibrium, an important task of conservation ecology may be to control it back into equilibrium. In the paper a trophic chain is considered, and control systems are obtained by changing certain model parameters into control variables. For the equilibrium control two approaches are proposed. First, for a fixed time interval, local controllability into equilibrium is proved, and applying tools of optimal control, it is also shown how an appropriate open-loop control can be determined that actually controls the system into the equilibrium in given time. Another considered problem is to control the system to a new desired equilibrium. The problem is solved by the construction of a closed-loop control which asymptotically steers the trophic chain into this new equilibrium. In this way, actually, a controlled regime shift is realized.

Keywords: trophic chains, controllability, optimal control, equilibrium control

1. Introduction

The concept of control of a trophic chain is used in different senses in the literature. A possible classification is: internal natural control, external natural control, external control by management. (For an overview of the different types of ecosystem control see Fath, 2004). Our study joins the research line concerning external, human control of trophic chains.

The human influence on ecosystems, in particular on population systems, is an important issue in conservation ecology. Moreover, sustainability of economic and social development in a broader sense also involves conservation aspects of ecology. On the one hand, ecosystems are often exposed to a strong human intervention, such as economic activity, wildlife management, fisheries or environmental pollution. On the
other hand, if the human activity breaks the equilibrium of the population system in
question, we can try to control it back to the previous or a new equilibrium.

These problems make it necessary to extend the traditional approach of theoretical
biology focusing only on a biological object, to the study of systems consisting of a
biological object and man that monitors or/and controls the biological object. This, in
dynamic situation, i.e. in case of a long-term human intervention, typically requires the
approach of mathematical systems theory (in frequently used terms, state-space
modelling), see Kalman et al. (1969) for the basic results of this theory, and Chen et al.
(2004) for a recent reference. This methodology offers solutions not only to controlling
but also to monitoring (i.e. observation) problems of population systems. While by now,
mathematical systems theory became quite familiar to system engineers, observability
and controllability analysis of dynamic models in population biology is relatively new.
The results on controllability and observability in frequency-dependent population
 genetics models are mostly based on the sufficient conditions obtained in Varga (1989),
(1990) and (1992), for the control and observation of systems with invariant manifold.
For the applications of these theorems see e.g. Kósa and Varga (1996), Scarelli and

For the control and monitoring problems of density-dependent population systems,
the corresponding mathematical tools can be found in Lee and Markus (1971);
conditions for controllability and observability problems for different Lotka-Volterra
type systems have been obtained e.g. in Varga et al. (2003), Gámez et al. (2008), López
et al. (2007). A recent general overview of the different applications of mathematical
systems theory in population biology is Varga (2008b).

In the present paper ecological systems of non-Lotka-Volterra type will be
considered, that form a trophic chain of type resource – producer – primary consumer,
see e.g. Svirezhev and Logofet (1983), Yodzis (1989). Stability and observability results
for such systems have been obtained in Shamandy (2005). We note that the monitoring
of a somewhat different, four-level ecological interaction chain of type resource –
producer – primary user – secondary consumer has been studied, applying the
mathematical results on verticum type systems, published in Molnár (1987), (1988a-e),

In Section 2, from Shamandy (2005), the model setup and basic conditions for the
existence and stability of an equilibrium of the system are shortly recalled. Section 3
and 4 is the main body of the paper. In Section 3 we prove the trophic chain is locally controllable into the equilibrium in given time. We also show how to calculate a corresponding open-loop control, applying the toolbox developed for MatLab in Banga, et al. (2005) and Hirmajer et al. (2009). In Section 4, based on results of Rafikov et al. (2008), we construct a closed-loop (actually a linear feedback) control that steers the system into a desired equilibrium. Section 5 is dedicated to the discussion of our results. Finally, in the Appendix we recall some basic concepts and results applied in the present paper.

2. Description of the dynamic model

For the presentation of our approach we consider a relatively simple food web, a trophic chain involving a resource, a plant and a herbivorous animal. In this section, from Shamandy (2005) we recall the dynamic model of a trophic chain of this type, see also Svirezhev and Logofet (1983), Jorgensen and Svirezhev (2004). For further details on trophic chains (and general food webs) we refer the reader to Yodzis (1989).

The considered model describes how a resource moves through a trophic chain. A typical terrestrial trophic chain consists of the following components:

- resource, the $0^{th}$ trophic level (solar energy or inorganic nutrient),
- which is incorporated by
- a plant population, the $1^{st}$ trophic level (producer),
- which transfers it to
- a herbivorous animal population, the $2^{nd}$ trophic level (primary consumer).

We note that for a similar study a longer trophic chain can also be considered, where the herbivore can be consumed by a predator population, the $3^{rd}$ trophic level (secondary consumer), which can be followed by top predator population (tertiary consumers). In the present paper, for technical simplicity, only trophic chains of the type resource – producer – primary consumer will be studied. According to the possible types of $0^{th}$ level (energy or nutrient), two types of trophic chains will be considered: open chains (without recycling) and closed chains (with recycling). At the $0^{th}$ trophic level, resource will be the common term for energy and nutrient.

Let us denote by $x_0$ the time-varying quantity of “free” resource present in the system, $x_1$ and $x_2$, in function of time, the biomass (or density) of the producer (species 1) and the primary consumer (species 2), respectively. Let $Q$ be the resource supply considered constant in the model. Let $\alpha_0 x_0$ be the velocity at which a unit biomass of
species 1 consumes the resource, and it is assumed that this consumption increases the
biomass of this species at rate $k_1$. A unit biomass of species 2 consumes the biomass of
species 1 at velocity $\alpha_1 x_1$, converting it into its own biomass at rate $k_2$. Both the plant
and the animal populations are supposed to decrease exponentially in the absence of the
resource and the other species, with respective rates of decrease (Malthus parameters)
$m_1$ and $m_2$.

Recycling can also be included in the model: In a closed system the dead
individuals of species 1 and 2 are recycled into free nutrient at respective rates
$0 < \beta_1 < 1$ and $0 < \beta_2 < 1$, while for an open system (where there is no natural recycling)
$\beta_1 = 0$, $\beta_2 = 0$ holds. (If only one of the $\beta$-s is positive, the system is called partially
closed.) Then with model parameters

\begin{equation}
Q, \alpha_0, \alpha_1, m_1, m_2 > 0; \ k_1, k_2 \in ]0,1[; \ \beta_1, \beta_2 \in [0,1[,
\end{equation}

the dynamic model for the trophic chain can be set up as follows:

\begin{align}
\dot{x}_0 &= Q - \alpha_0 x_0 x_1 + \beta_1 m_1 x_1 + \beta_2 m_2 x_2 \quad (2.2) \\
\dot{x}_1 &= x_1(-m_1 + k_1 \alpha_0 x_0 - \alpha_1 x_2) \quad (2.3) \\
\dot{x}_2 &= x_2(-m_2 + k_2 \alpha_1 x_1) \quad (2.4)
\end{align}

Let function $f$ be defined in terms of the right-hand side of this system:

\begin{equation}
f : \mathbb{R}^3 \to \mathbb{R}^3, \quad f(x) = f(x_0, x_1, x_2) := \left[ \begin{array}{c}
Q - \alpha_0 x_0 x_1 + \beta_1 m_1 x_1 + \beta_2 m_2 x_2 \\
x_1(-m_1 + k_1 \alpha_0 x_0 - \alpha_1 x_2) \\
x_2(-m_2 + k_2 \alpha_1 x_1)
\end{array} \right].
\end{equation}

In Shamandy (2005), a necessary and sufficient condition has been obtained for
the coexistence of the population system. The latter means that there exists a non-trivial
ecological equilibrium $x^*$ of dynamic system (2.2)-(2.4), where all components are
present: system (2.2)-(2.4) has a unique equilibrium $x^* = (x^*_0, x^*_1, x^*_2) > 0$ if and only if
the resource supply is high enough, i.e.

\begin{equation}
Q > Q_z := \frac{m_1 m_2}{\alpha_1 k_2} \frac{\beta_1 m_1 m_2}{\alpha_1 k_2},
\end{equation}

and then the respective equilibrium values for the resource, plant and herbivore are
Throughout the paper condition (2.5) will be supposed.

**Remark 2.1.** For $\beta_1 > 0$ the threshold $Q_2$ is lower than for $\beta_1 = 0$. Clearly, in the latter case the lack of recycling from species 1, a higher value of resource supply is necessary to produce the required positive equilibrium.

**Remark 2.2.** It can be shown that, under the same condition the stable coexistence is also guaranteed, or in mathematical terms, this equilibrium $x^*$ is asymptotically stable. In order to guarantee this stable coexistence $x^*$, we shall suppose throughout the paper that condition (2.5) holds.

**Example 2.3.** For an illustration, we consider system (2.2)-(2.4) with parameters

$Q := 10; \alpha_0 := 0.3; \alpha_1 := 0.1; \beta_1 := 0.2; \beta_2 := 0.3; m_1 := 0.1; m_2 := 0.4; k_1 := 0.5; k_2 := 0.5.$

Checking condition (2.5), we get $Q > Q_2 = 1.44$, therefore in this case the considered system (2.2)-(2.4) has a positive equilibrium $x^* = (4.52, 8, 5.78)$ calculated from (2.6)-(2.8), which is asymptotically stable (see Figure 1).
3. **Open-loop control of the trophic chain into equilibrium in given time**

In this section we will deal with the following problem. Let us suppose that the system is deviated from its equilibrium, and we want to steer it back into equilibrium by changing certain model parameters into control variables. In mathematical terms this means that to the reference value of a model parameter (resource supply, recycling rate or Malthus parameter), a time-dependent control function is added. **Open-loop control** means that we want to determine in advance a control in function of time, such that the corresponding time-dependent state of the system reaches the original equilibrium in given time. (The **closed-loop controls** to be considered in the next section will depend on the current state of the system.)

**Case 1. Control of the resource supply**

Let us suppose first that the resource supply is controlled in function of time in the form \( Q + u(t) \), considering control functions \( u \) defined on a fixed interval \([0, T]\). Then our model (2.2)-(2.4) takes the form

\[
\begin{align*}
\dot{x}_0 &= Q + u(t) - \alpha_0 x_0 x_1 + \beta_1 m_1 x_1 + \beta_2 m_2 x_2 \\
\dot{x}_1 &= x_1(-m_1 + k_1 \alpha_0 x_0 - \alpha_1 x_2) \\
\dot{x}_2 &= x_2(-m_2 + k_2 \alpha_1 x_1).
\end{align*}
\]

Then (3.1)-(3.3) can be considered as a control system, and in terms of the notation of the Appendix, with
$F : \mathbb{R}^4 \to \mathbb{R}^3, \quad F(x_0, x_1, x_2, u) := \begin{bmatrix} Q + u - \alpha_0 x_0 x_1 + \beta_1 m_i x_1 + \beta_2 m_2 x_2 \\ x_1(-m_i + k_i \alpha_0 x_0 - \alpha_2 x_2) \\ x_2(-m_2 + k_2 \alpha_2 x_1) \end{bmatrix}$

Control system (3.1)-(3.3) takes the form

$$\dot{x} = F(x, u^* + u(t))$$

(3.4)

Obviously, to $u^* := 0$ and $u(t) := 0$ ($t \in [0, T]$), there corresponds the non-trivial ecological equilibrium $x^*$ of dynamic system (2.2)-(2.4).

Now we show that control system (3.4) is locally controllable to $x^*$ on $[0, T]$.

For the application of Theorem A.2 of the Appendix, let us calculate the Jacobians

$$A := D_1 F(x^*, 0) = \begin{bmatrix} -\alpha_0 x_1^* & -\alpha_0 x_0^* + \beta_1 m_i & \beta_2 m_2 \\ k_i \alpha_0 x_1^* & 0 & -\alpha_2 x_2^* \\ 0 & k_2 \alpha_2 x_2^* & 0 \end{bmatrix}, \quad B := D_2 F(x^*, 0) = \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$  

Since

$$\det[B \mid AB \mid A^2 B] = \alpha_0^2 \alpha_i k_i^2 k_2 x_1^* x_2^* \neq 0,$$

we get $\text{rank}[B \mid AB \mid A^2 B] = 3$, and applying Theorem A.2 we obtain the local controllability of system (3.1)-(3.3) into $x^*$ on interval $[0, T]$.

The obtained local controllability means that from nearby states, the system can be steered into the equilibrium applying an appropriate small control $\bar{u} \in U_{\epsilon_0}[0, T]$.

Now we proceed to the determination of such a control.

Fix an initial state $x^0$ from a neighbourhood of local controllability of system (3.4), and for each control function $u$ small enough (i.e. $u \in U_{\epsilon_0}[0, T]$, see conditions of system (A1)-(A2) of the Appendix), let $x$ be the solution of (3.4), defined on $[0, T]$ and corresponding to the initial value $x^0$. Then a control $u = \bar{u}$ will steer initial state $x^0$ into equilibrium $x^*$, if and only if it minimizes the functional

$$\Phi(u) := ||x(T) - x^*||^2.$$

The above reasoning can be summarized in the following theorem:

**Theorem 3.1.** For any parameter values (2.1), system (3.1)-(3.3) is locally controllable into equilibrium $x^*$ on interval $[0, T]$, and an initial state $x^0$ will be steered
into \( x^* \) by a control \( u \in U_{\alpha_k}[0,T] \) if and only if the latter is a solution of the following optimal control problem:

\[
\Phi(u) := \left| x(T) - x^* \right|^2 \rightarrow \min, \tag{3.5}
\]

\[
u \in U_{\alpha_k}[0,T], \ x(0) = x^0, \tag{3.6}
\]

\[
\dot{x} = F(x, u^* + u(t)). \tag{3.7}
\]

**Remark 3.2.** From the local controllability of the control system (3.4), we know that the optimal control problem (3.5)-(3.7) has at least one solution.

As a consequence of this theorem, for an effective calculation of an equilibrium control \( \pi \), it is enough to solve the optimal control problem (3.5)-(3.7). To this end we can apply the toolbox developed for MatLab in Banga, et al. (2005) and Hirmajer et al. (2009). Next, using this toolbox we will illustrate the results of Theorem 3.1.

**Example 3.3.** Let us consider system (3.1)-(3.3) with parameters of Example 2.3:

\[
Q = 10; \ \alpha_0 := 0.3; \ \alpha_1 := 0.1; \ \beta_1 := 0.2; \ \beta_2 := 0.3; \ m_1 := 0.1; \ m_2 := 0.4; \ k_1 := 0.5; \ k_2 := 0.5. \tag{3.8}
\]

Taking as initial condition \( x^0 := (4, 7, 5) \) and time interval \( T := 5 \), we apply the MatLab toolbox mentioned above. Figure 2a shows the solution \( \bar{u} \) of the optimal control problem, the corresponding solution \( x^* \), ending at equilibrium \( x^* = (4.52, 8, 5.78) \) calculated in Example 2.3. can be seen in Figure 2b.

![Figure 2a](image-url)
We note that, since by Remark 2.2, for the uncontrolled system, $x^*$ is asymptotically stable, the state would tend to $x^*$, reaching it in “infinite time”, as seen in Figure 2.c. By our method the system state is steered into $x^*$ in given finite time.

Case 2. Control of a recycle rate

For the equilibrium control of the trophic chain, another possibility is to introduce the control in one of the recycling rates, e.g. $\beta_1$. In this case the controlled system is of the form

$$\dot{x}_0 = Q - \alpha_x x_0 x_1 + (\beta_1 + u(t))m_1 x_1 + \beta_2 m_2 x_2$$

(3.8)
\[ \begin{align*}
\dot{x}_1 &= x_1(-m_1 + k_1\alpha_0 x_0 - \alpha_i x_2) \\
\dot{x}_2 &= x_2(-m_2 + k_2\alpha_1 x_1). 
\end{align*} \tag{3.9} \tag{3.10}
\]

Proceeding similarly to Case 1, with definition

\[ F : \mathbb{R}^3 \to \mathbb{R}^3, \quad F(x_0, x_1, x_2, u) := \begin{bmatrix}
Q - \alpha_0 x_0 x_1 + (\beta_1 + u)m_1 x_1 + \beta_2 m_2 x_2 \\
x_1(-m_1 + k_1\alpha_0 x_0 - \alpha_i x_2) \\
x_2(-m_2 + k_2\alpha_1 x_1)
\end{bmatrix}, \]

control system (3.8)-(3.10) takes the form

\[ \dot{x} = F(x, u^* + u(t)). \]

The linearization process results in the same matrix \( A \) as in Case 1, but in a different

\[ B = \begin{bmatrix} m_1 x_1^* \\ 0 \\ 0 \end{bmatrix}. \]

Now

\[ \det[B \ | \ AB \ | \ A^2 B] = \alpha_0^2 \alpha_0 k_2^2 k_1^2 m_1^3 x_1^* x_2^* \neq 0, \]

therefore \( \text{rank}[B \ | \ AB \ | \ A^2 B] = 3 \), and hence without any further assumption on the model parameters (2.1) Theorem A.2 implies local controllability of system (3.8)-(3.10) into \( x^* \) on interval \([0, T]\).

**Case 3. Changing Malthus parameter into control variable**

For this case, as example, let us consider the control of the birth rate of the plant species. The obtained control system is

\[ \begin{align*}
\dot{x}_0 &= Q - \alpha_0 x_0 x_1 + \beta_1 m_1 x_1 + \beta_2 m_2 x_2 \\
\dot{x}_1 &= x_1(-m_1 + u(t) + k_1\alpha_0 x_0 - \alpha_i x_2) \\
\dot{x}_2 &= x_2(-m_2 + k_2\alpha_1 x_1) .
\end{align*} \]

Following the reasoning of the previous cases, matrix \( A \) again is the same as in Case 1, whereas for \( B \) we get

\[ B = \begin{bmatrix} 0 \\ x_1^* \\ 0 \end{bmatrix}. \]

Since condition \( \beta_1 m_1 \leq \alpha_0 x_0^* \) implies

\[ \det[B \ | \ AB \ | \ A^2 B] = \alpha_0 \alpha_0 k_2^2 x_1^* x_2^* (\alpha_0 x_0^* - \beta_1 m_1) + \beta_2 m_2 k_2^2 \alpha_1^2 x_1^* x_2^* \neq 0, \]
and hence \( \text{rank}[B \mid AB \mid A^2B] = 3 \), applying again Theorem A.2 of the Appendix, we obtain the following sufficient condition for the equilibrium control:

**Theorem 3.4.** If the recycling rate of the plant is small enough \( \beta_i \leq \frac{\alpha_0 x_i^*}{m_i} \), then the trophic chain can be controlled to equilibrium, and an open-loop control can be found by solving an optimal control problem of the form (3.5)-(3.7).

**4. Closed-loop control to a new equilibrium**

Let us suppose that in an ecosystem over the past period an undesired stationary state has been formed. Then the objective of ecosystem management may be to control the system to a state where a given state component has a desired value, and keep it there in equilibrium, applying a constant control. Actually, in this way a controlled *regime shift* is realized.

To this end we will find a closed-loop (actually a linear feedback) control that asymptotically steers the system state. Unlike the open-loop control, where the intervention is calculated on beforehand, closed loop control means that at every moment the control to be applied is calculated from the current state of the system. For the construction we will follow the optimal control methodology of Rafikov et al. (2008), recalled in the Appendix.

The control of the trophic chain can be realized at different trophic levels. Below we present two possibilities: intervention either on the herbivore or on the plant, by adding or eliminating individuals of these populations.

**4.1. Steering the plant population to a given level by controlling the herbivore**

Let us suppose that we want to achieve a desired level \( x_{1d}^* \) of the plant species and keep it there in the long run, by means of changing the presence of the herbivore animal. Formally, let us consider the following control system

\[
\begin{align*}
\dot{x}_0 &= Q - \alpha_0 x_0 x_1 + \beta_i m_1 x_1 + \beta_2 m_2 x_2 \\
\dot{x}_1 &= x_1 (-m_1 + k_1 \alpha_0 x_0 - \alpha_i x_1) \\
\dot{x}_2 &= x_2 (-m_2 + k_2 \alpha_i x_i) + U
\end{align*}
\]  

(4.1)

where \( U \) is a continuous control function. Given \( x_{1d}^* \), by solving system (4.2) below, we find an equilibrium \( x_d^* = (x_{0d}^*, x_{1d}^*, x_{2d}^*) \) and a corresponding constant control \( u_d^* \in \mathbb{R} \) that would keep system (4.1) in equilibrium \( x_d^* \).
\[ Q - \alpha_0 x_{id}^* x_{id}^* + \beta_1 m_1 x_{id}^* + \beta_2 m_2 x_{id}^* = 0 \]
\[ x_{id}^* (-m_1 + k_1 \alpha_0 x_{id}^* - \alpha_1 x_{id}^*) = 0 \]  \hspace{1cm} (4.2)
\[ x_{id}^* (-m_2 + k_2 \alpha_1 x_{id}^*) + u^* = 0 \]

Then, from (4.1) and (4.2), for the new variables, 
\[ y = x - x_d^* , \ u = U - u^* , \]
we easily get the error system:
\[ \dot{y} = \hat{A} y + q(y) + \hat{B} u , \]  \hspace{1cm} (4.3)
where matrices \( \hat{A} \) and \( \hat{B} \) and the vector \( q(y) \) are defined as follows:
\[
\hat{A} = \begin{bmatrix}
-\alpha_0 x_{id}^* & -\alpha_0 x_{id}^* & \beta_1 m_1 \\
k_1 \alpha_0 x_{id}^* & 0 & -\alpha_1 x_{id}^* \\
0 & k_2 \alpha_1 x_{id}^* & -m_2 + k_2 \alpha_1 x_{id}^*
\end{bmatrix},
\hat{B} = \begin{bmatrix}
0 \\
0 \\
1
\end{bmatrix},
q(y) = \begin{bmatrix}
-\alpha_0 y_0 y_1 \\
k_1 \alpha_0 y_0 y_1 - \alpha_1 y_1 y_2 \\
k_2 \alpha_1 y_1 y_2
\end{bmatrix}. \]  \hspace{1cm} (4.4)

Now, in order to apply Theorem A.3 of Rafikov et al. (2008) (see Appendix), it is enough to find positive definite matrices \( P, R, S \in \mathbb{R}^{3 \times 3} \), \( P \) and \( S \) symmetric, such that \( P \) satisfies the matrix Riccati equation
\[ P \hat{A} + \hat{A}^T P - P \hat{B} R^{-1} \hat{B}^T P + S = 0, \]  \hspace{1cm} (4.5)
and function
\[ l(y) := y^T S y - q^T (y) P y - y^T P q(y) \]  \hspace{1cm} (y \in \mathbb{R}^3) \hspace{1cm} (4.6)
is positive definite.

At this point we will need the following lemma.

**Lemma 4.1.** For any matrix \( P \in \mathbb{R}^{3 \times 3} \) and
\[
S := \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}, \quad q(y) := \begin{bmatrix}
-\alpha_0 y_0 y_1 \\
k_1 \alpha_0 y_0 y_1 - \alpha_1 y_1 y_2 \\
k_2 \alpha_1 y_1 y_2
\end{bmatrix}.
\]

function \( l \) defined in (4.6) attains a strict local minimum at the origin (0,0,0).

**Proof.** In the considered case, for all \( y \in \mathbb{R}^3 \) we have
\[
l(y) = y_0^2 (1 + \alpha_0 (p_{11} + k_1 (-p_{12} + p_{21}))y_1) + y_2^2 + (\alpha_0 p_{11} + \alpha_1 (p_{23} + p_{32}))y_1 y_2^2 + \\
y_1^2 (1 + \alpha_0 p_{12} y_2 + \alpha_1 (2 p_{22} - k_2 (p_{23} + p_{32}))y_2) + \\
y_0 y_1 (\alpha_1 (p_{12} - k_2 (p_{13} - p_{31}) + p_{21})y_2 + \alpha_0 (p_{21} y_1 + (p_{11} + k_1 (p_{23} - p_{32}) + p_{31})y_2)),
\]
and its first order partial derivatives are
\[
D_0 l(y) = 2 y_0 (1 + \alpha_0 (p_{11} - k_1 (p_{12} - p_{21}))y_1) + y_1 (\alpha_1 (p_{12} - k_2 (p_{13} - p_{31}) + p_{21})y_2 +
\]
\[ D_1 l(y) = \alpha_0 (p_{11} + k_1 (-p_{12} + p_{21})) y_0^2 + \alpha_0 p_{21} y_0 p_1 + \alpha_0 (p_{13} + \alpha_1 (p_{23} + p_{32})) y_2^2 + 2 y_1 (1 + \alpha_0 p_{12} y_2 + \alpha_1 (2 p_{22} - k_2 p_{23} - p_{32})) y_3 + y_0 \alpha_1 (p_{12} - k_2 (p_{13} - p_{31}) + p_{21}) y_2^2 + \alpha_0 (p_{21} y_1 + (p_{11} + k_1 (p_{23} - p_{32}) + p_{31}) y_2^2 \]

\[ D_2 l(y) = \alpha_1 (p_{12} + p_{21} - k_1 (p_{13} - p_{31})) + \alpha_0 (p_{11} + k_1 (p_{23} - p_{32})) y_0 y_1 + \alpha_2 (p_{12} + \alpha_1 (2 p_{22} + k_2 (-p_{23} + p_{32})) y_1^2 + 2 y_2 + 2 (\alpha_0 p_{13} + \alpha_1 (p_{23} + p_{32})) y_1 y_2. \]

Obviously

\[ D_0 l(0) = D_1 l(0) = D_2 l(0) = 0, \]

and for the Hessian of \( l \) at the origin we have

\[ HI(0) = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix}, \]

which is obviously positive definite, implying that the origin is a strict local minimum point of function \( l \). \( \blacksquare \)

Now, from the above reasoning, combining Theorem A.3 with Corollary A.6 of Appendix, we obtain the following theorem.

**Theorem 4.2.** Suppose that there exist positive definite matrices \( P, R \in \mathbb{R}^{3 \times 3} \), \( P \) symmetric, such that with matrices \( \hat{A}, \hat{B} \) defined in (4.4), \( P \) is a solution of the matrix Riccati equation (4.5). Then the linear feedback

\[ u(y) := -R^{-1} \hat{B}^T Py \quad (y \in \mathbb{R}^3) \quad (4.7) \]

asymptotically steers any initial state \( y(0) \) into zero. In particular, there exists a neighbourhood \( V \) of zero in \( \mathbb{R}^3 \) such that for all initial value \( x(0) \in V \) and control \( U = u^* + u \), for the solution \( x \) of system (4.1) we have \( \lim_{\infty} x = x_{d}^* \).

Let us consider now an illustrative example.

**Example 4.3.** Let us start from the uncontrolled system (2.2)-(2.4) with the same model parameters as in Example 2.3. As we have seen, system (2.2)-(2.4) has a positive equilibrium \( x^* = (4.52, 8, 5.78) \), which is asymptotically stable.

Let us assume that we want to steer the biomass level to a desired level \( x_{1d}^* = 4 \), intervening on the herbivore animal. From system of algebraic equations (4.2), we calculate \( x_{0d}^* \), \( x_{2d}^* \) and \( u^* \), obtaining \( x_{d}^* = (9.76, 4, 13.65) \), \( u^* = 2.73 \).
For matrices $\hat{A}$ and $\hat{B}$ defined in (4.4) we have

$$\hat{A} = \begin{bmatrix} -1.2 & -2.91 & 0.12 \\ 0.6 & 0 & -0.4 \\ 0 & 0.68 & -0.2 \end{bmatrix}; \quad \hat{B} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

and choosing

$$S := \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad R := \begin{bmatrix} 1 \end{bmatrix},$$

we calculate matrix $P$ from the Riccati equation (4.5) using the Matlab 7.6 command LQR, obtaining

$$P = \begin{bmatrix} 0.47 & 0.12 & -0.05 \\ 0.12 & 2.59 & -0.23 \\ -0.05 & -0.23 & 0.9 \end{bmatrix}.$$}

Obviously $P$ and $Q$ are positive definite symmetric matrices. Now, for the auxiliary function $l$ we obtain

$$l(y) = y_0^2 (1+0.14y_1) + y_0 y_1 (0.36 y_1 + 0.19 y_2) + y_1^2 (1+0.55 y_2) + y_2^2 - 0.061 y_1 y_2^2,$$

and its local definiteness is illustrated in Figure 3.

![Figure 3. 3D sections of $l$ at the origin](image)

Applying Theorem 4.2, the feedback control

$$u(y) = 0.05 y_0 + 0.23 y_1 - 0.9 y_2$$

asymptotically steers the error system (4.3) to 0, implying that for the solution $x$ of system (4.1) with the closed-loop control $U(x) := u^* + u(x - x^*)$, we have

$$\lim_{x^*} x = x^* = (9.76, 4, 13.65),$$

as shown in Figure 4.
4.2. Steering the animal population by controlling the plant

Let us consider now the problem which in certain sense is the opposite to the previous one. We want to achieve a desired level $x^{*}_{2d}$ of the animal population and keep it there in a stationary regime, means of changing the presence of the plant species.

The corresponding control system then is

$$
\begin{align*}
\dot{x}_0 &= Q - \alpha_0 x_0 x_1 + \beta_1 m_1 x_1 + \beta_2 m_2 x_2 \\
\dot{x}_1 &= x_1 (-m_1 + k_1 \alpha_0 x_0 - \alpha_1 x_2) + U \\
\dot{x}_2 &= x_2 (-m_2 + k_2 \alpha_1 x_1)
\end{align*}
$$

(4.8)

where $U$ is again, a continuous control function. We suppose that to a constant control $u^* \in R$, there corresponds a desired state $x^*_d$, i.e.,

$$
\begin{align*}
Q - \alpha_0 x_0^* x_1^* + \beta_1 m_1 x_1^* + \beta_2 m_2 x_2^* &= 0 \\
x_1^* (-m_1 + k_1 \alpha_0 x_0^* - \alpha_1 x_2^*) + u^* &= 0 \\
x_2^* (-m_2 + k_2 \alpha_1 x_1^*) &= 0
\end{align*}
$$

(4.9)

Reasoning in a way analogous to the previous case, applying Theorem 4.2 we can find an appropriate control that steers the system into the desired new equilibrium state, which can be seen in the following illustrative example.

**Example 4.4.** We consider the same model parameters of Examples 2.3 and 4.3 that imply the positive asymptotically stable equilibrium $x^* = (4.52, 8, 5.78)$. Now, we intervene on the plant species in order to steer the herbivore population to a higher level,
From system (4.9) we calculate the constant control \( u^* \), and the rest of coordinates corresponding to the desired state, obtaining \( x^*_i = (4.73, 8, 10) \); \( u^* = 3.12 \).

Matrices \( \hat{A} \) and \( \hat{B} \) in this case are

\[
\hat{A} = \begin{bmatrix}
-2.4 & -1.4 & 0.12 \\
1.2 & 0 & -0.8 \\
0 & 0.5 & 0
\end{bmatrix}; \quad \hat{B} = \begin{bmatrix}
0 \\
1 \\
0
\end{bmatrix}.
\]

Choosing \( S \) and \( R \) the same as in Example 4.3 and calculating matrix \( P \) from the corresponding Riccati equation we obtain

\[
P = \begin{bmatrix}
0.31 & 0.22 & 0.14 \\
0.22 & 0.93 & 0.49 \\
0.14 & 0.49 & 2.74
\end{bmatrix}.
\]

Now, from formula (4.7) the linear feedback for the error system is

\[
u(y) = -0.22y_0 - 0.93y_1 - 0.49y_2,
\]

and hence, for system (4.8) the required closed-loop \( U(x) := u^* + u(x - x^*_i) \) can be obtained. The resulting solution of the controlled system can be seen in Figure 5.

**Figure 5.** Solution of system (4.8) with parameters of Example 2.3, and initial value \( x(0) = x^* = (4.52, 8, 5.78) \)

### 4. Discussion

In the paper a control-theoretic methodology has been proposed for a particular tasks of ecosystem management. We have shown how the technique of optimal control theory can be applied to deal with qualitative properties like open- or closed-loop equilibrium control of ecological systems. For the different tasks we used different
approaches: the constructed open-loop control substitutes certain model parameter, while the closed-loop control necessarily acts on the state variables.

In Petrosjan and Zakharov (1997) the controllability of predator-prey was already considered, but only with constant control. In Varga (2008b), sufficient condition it was obtained for a Lotka-Volterra system to locally controllable into equilibrium, but no method was proposed to calculate the existing equilibrium control. Concerning the open-loop equilibrium control, the novelty of our paper is that for the considered trophic chain, an efficient method for the calculation of the equilibrium control is proposed, by setting up and solving an optimal control problem.

In Rafikov et al. (2008), an optimal feedback control was used in order to steer a Lotka-Volterra type predator-prey system asymptotically into a given equilibrium, in the context of biological pest control. We have shown, instead, that a similar approach can be also applied to find a closed-loop equilibrium control of a non-Lotka-Volterra type trophic chain into a new equilibrium, realizing a controlled regime shift.

In the present paper the proposed methodology has been used for the control of simple trophic chain. However, it can be also applied to different types of multi-species dynamic population models, see e.g. Yodzis (1989), Cressman et al. (2001), Cressman and Garay (2003), (2006), (2009), Garay et al. (2003), Cressman et al. (2004), Garay (2002), (2009).

Appendix

Controllability of nonlinear systems

First, from Lee and Markus (1971), we recall some concepts and a theorem of nonlinear control theory. Given $m, s \in \mathbb{N}$, let $F : \mathbb{R}^m \times \mathbb{R}^s \to \mathbb{R}^m$ be a continuously differentiable function. For a reference control value $u^* \in \mathbb{R}^s$, let $x^* \in \mathbb{R}^m$ be such that $F(x^*, u^*) = 0$. For technical reason we shall need a rather general class of controls. Let us fix a time interval $[0, T]$, and for each $\varepsilon \in \mathbb{R}^+$ define the class of essentially bounded $\varepsilon$-controls

$U_\varepsilon[0, T] := \{u \in L_\varepsilon^1[0, T] \mid \|u(t)\|_u \leq \varepsilon \text{ for almost every } t \in [0, T]\}.$

Then it can be shown that there exists $\varepsilon_0 \in \mathbb{R}^+$ such that for all $u \in U_{\varepsilon_0}[0, T]$ and $x^0 \in \mathbb{R}^m$ with $\|x^0 - x^*\| < \varepsilon_0$ the initial value problem

$$
$$
\[ \dot{x}(t) = F(x(t), u^* + u(t)) \quad (\text{for a.e. } t \in [0, T]) \]  
\[ x(0) = x^0 \]  
(A.1)  
(A.2)

has a unique solution. We notice that \( x^* \) is an equilibrium state for the zero-control system.

**Definition A.1.** Control system (A.1)-(A.2) is said to be *locally controllable to \( x^* \) on \([0, T]\)*, if there exists \( \varepsilon \in ]0, \varepsilon_0]\) such that for all \( x^0 \) from the \( \varepsilon \)-neighbourhood of \( x^* \), there is a control \( u \in U, [0, T] \) that controls the initial state \( x^0 \) to equilibrium \( x^* \), i.e. for the solution \( x \) of the initial value problem (A.1)–(A.2), equality \( x(T) = x^* \) holds.

Let us linearize system (A.1)-(A.2) around \((x^*, u^*)\), introducing the corresponding Jacobians

\[ A := D_1 F(x^*, u^*), \quad B := D_2 F(x^*, u^*). \]

Then we have the following sufficient condition for local controllability:

**Theorem A.2** (Lee and Markus, 1971)

If \( \text{rang}[B, AB, A^{n-1}B] = n \) then system (A.1)-(A.2) is locally controllable to \( x^* \) on \([0, T]\).

*Closed-loop asymptotic control into equilibrium in nonlinear systems*

Now, from Rafikov et al. (2008) we recall the construction of a linear closed-loop control that asymptotically steers the system into a desired equilibrium. For given \( n, r \in \mathbb{N}, \hat{A} \in \mathbb{R}^{n \times n}, \hat{B} \in \mathbb{R}^{n \times r} \) and continuously differentiable function \( g: \mathbb{R}^n \rightarrow \mathbb{R}^n \), consider the control system

\[ \dot{x} = \hat{A} x + g(x) + \hat{B} U, \]  
(A.3)

where \( U \) is a continuous control function. Assume that to a constant control \( u^* \in \mathbb{R}^r \), there corresponds an equilibrium state \( x^* \), i.e.,

\[ \hat{A} x^* + g(x^*) + \hat{B} u^* = 0. \]  
(A.4)

Then, from (A.3) and (A.4), with substitutions

\[ y := x - x^*; \quad u := U - u^* \]

we obtain

\[ \dot{y} = \hat{A} y + q(y) + \hat{B} u, \quad \text{where} \quad q(y) := g(y + x^*) - g(x^*). \]  
(A.5)

Below a feedback control will be given which asymptotically steers system (A.5) into the zero equilibrium.
Theorem A.3 (Rafikov et al. 2008). If there exist positive definite matrices $P, R, S \in \mathbb{R}^{n \times n}$, $P$ and $S$ symmetric, such that the function

$$l(y) := y^T Sy - q^T (y)Py - y^T Pq(y) \quad (y \in \mathbb{R}^n)$$

is positive definite, and $P$ satisfies the equation

$$P\hat{A} + \hat{A}^T P - P\hat{B}R^{-1}\hat{B}^T P + S = 0.$$  

Then the linear feedback

$$u(y) = -R^{-1}\hat{B}^T P y \quad (y \in \mathbb{R}^n) \quad (A.6)$$

asymptotically steers any initial state $y(0)$ into zero.

Remark A.4. The statement $\lim_{\infty} y = 0$ is obviously equivalent to $\lim_{\infty} x = x^*$.

Remark A.5. According to Rafikov et al. 2008, the feedback control (A.6) also minimizes the functional

$$I(y) := \int_0^\infty [l(y(t)) + u^T(y(t))Ru(y(t))]dt,$$

however, we will not use this statement.

Corollary A.6. (Gámez et al. 2009) Using the notation of the previous Theorem A.3, let us suppose that function $l$ is locally positive definite. Then there exists a neighbourhood $V$ of zero in $\mathbb{R}^n$ such that for all initial value $x(0) \in V$, for the solution $x$ of system (A.6) we have $\lim_{\infty} x = x^*$.
